PART 2 : CDO and customized PBNtoFinal 14h30-15h00

Local collaborative work @ Nice between ATC and Air France on CDO and PBN

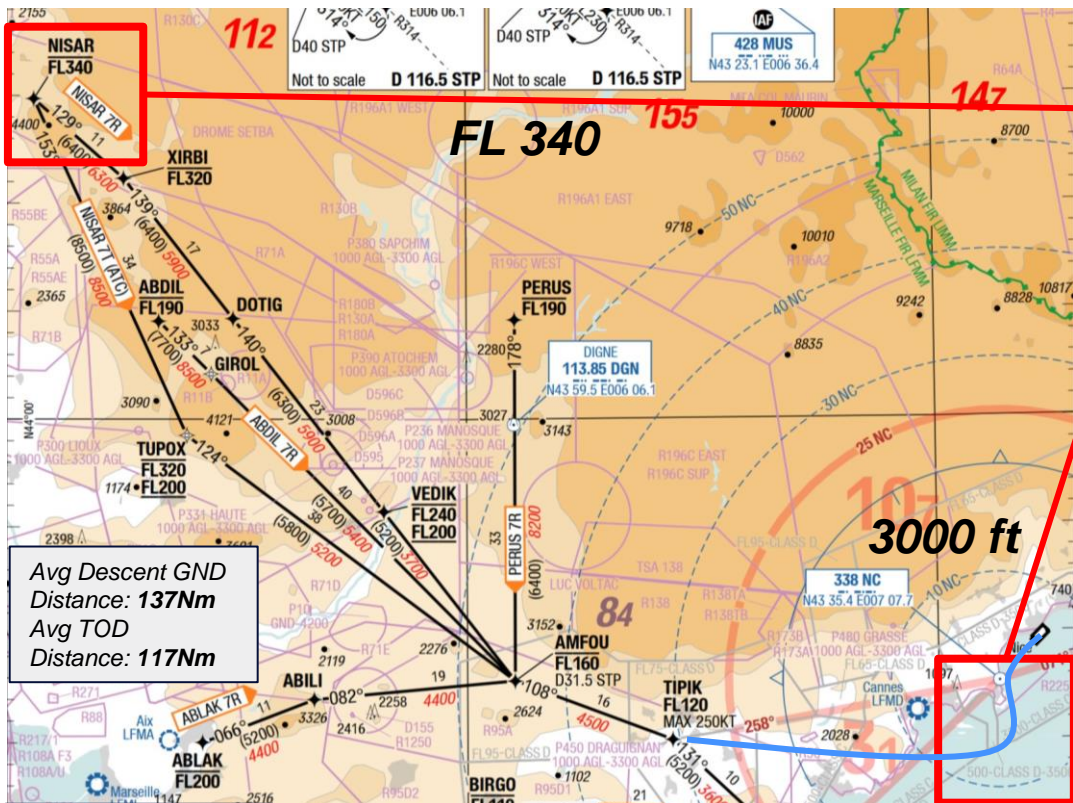

PBN to Final : Closed trajectories for VFE improvement (CDO 195)

PRESENT SEQUENCING SITUATION

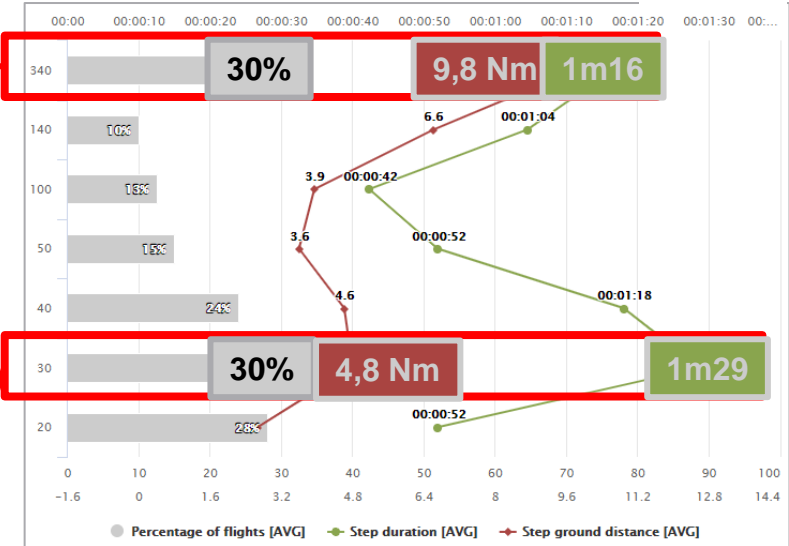

- STARs :
too long to be flown during
low trafic period
- Frequent Vectoring from
TIPIK or AMGEL
- Distance To Go often
requested by crew

04 L/R arrivals via NISAR* - 2019 Air France analysis

NCE • Avg step ground distance • Avg step duration

04 L/R **9 NM** **2 MIN 17 S**

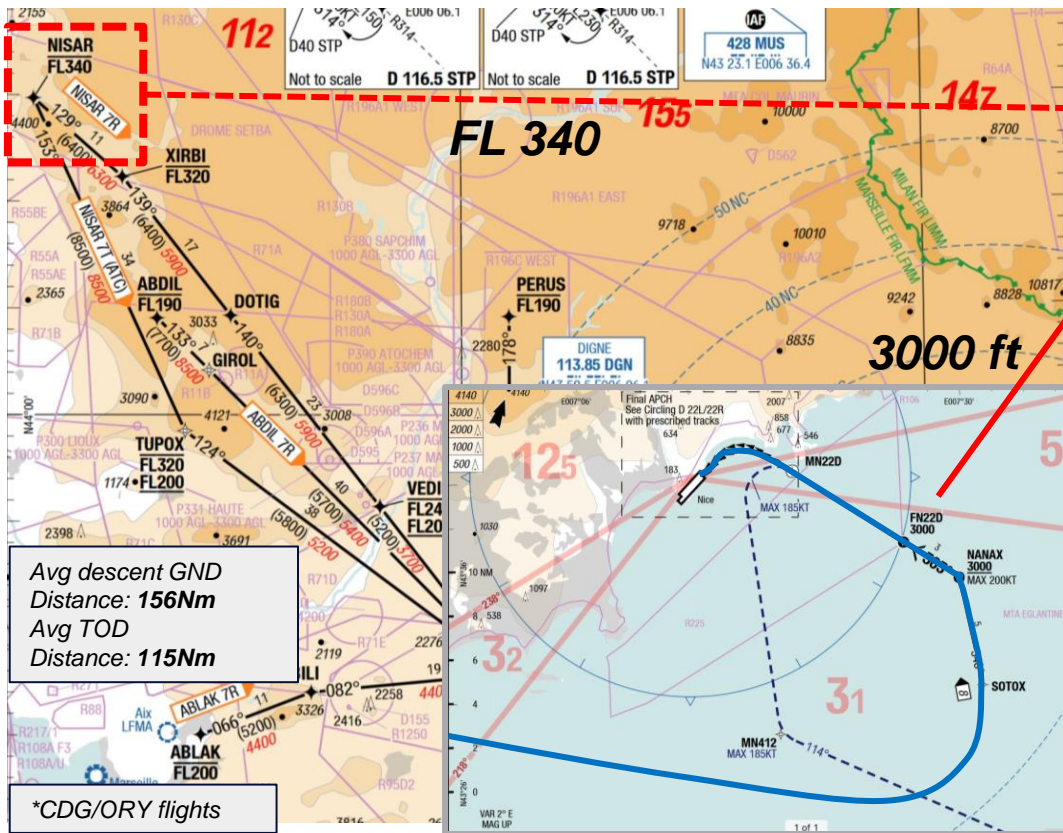

2 main level off segments :

- **FL 340** : NISAR constraint – ACC
- **3000 ft** : Low traffic => short vectoring – extended use of speedbrake (>2 min)
High traffic => low level off – variable vectoring

=> Objective = PREDICTABILITY

22 L/R arrivals via NISAR* - 2019 Air France analysis

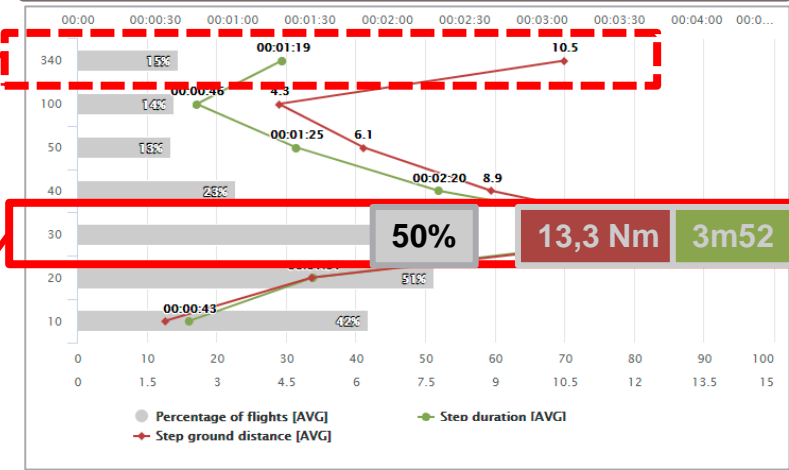

Avg descent GND
Distance: 156Nm
Avg TOD
Distance: 115Nm

*CDG/ORY flights

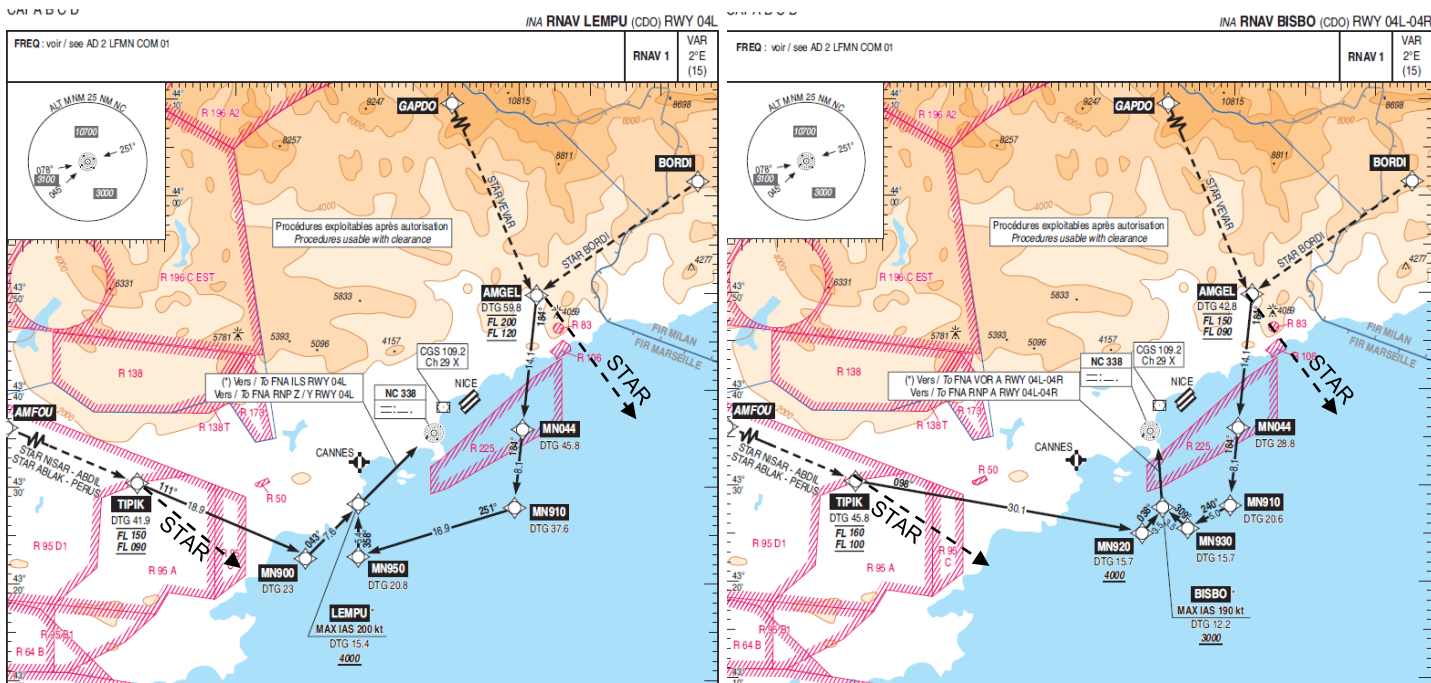

NCE • Avg step ground distance • Avg step duration

22 L/R **19 NM** **5 MIN**

- Longer descent ground distance – longer vectoring
 - **More** flights impacted by **longer & lower** level off segments
 - No predictability on DTG and sequencing
- => Possibility to adapt the descent with **earlier trajectory closing**

Former CDO charts

Conditions of use :

- Only at night
- With ATC clearance
- Starting from mid-STARs

In real : 

- Never used in a proper manner
- Often followed during the day by mistake
- **Induced unexpected tracks**

Withdrawal in 2020 and commitment to work on a new version of CDO

New PBN to Final project to improve NCE CDO application

- Nov 2021 : start of a collaborative work with Air France - Green Task Force
- March/Nov 22 : workshop for design, working methods, trials (ATCOs + Air France)
- No trial participation of ACC above TMA (expected in 2024...)

Target :

- CDO 195 (from first contact in Nice TMA to ground)
- Low, Medium traffic

Safety objectives :

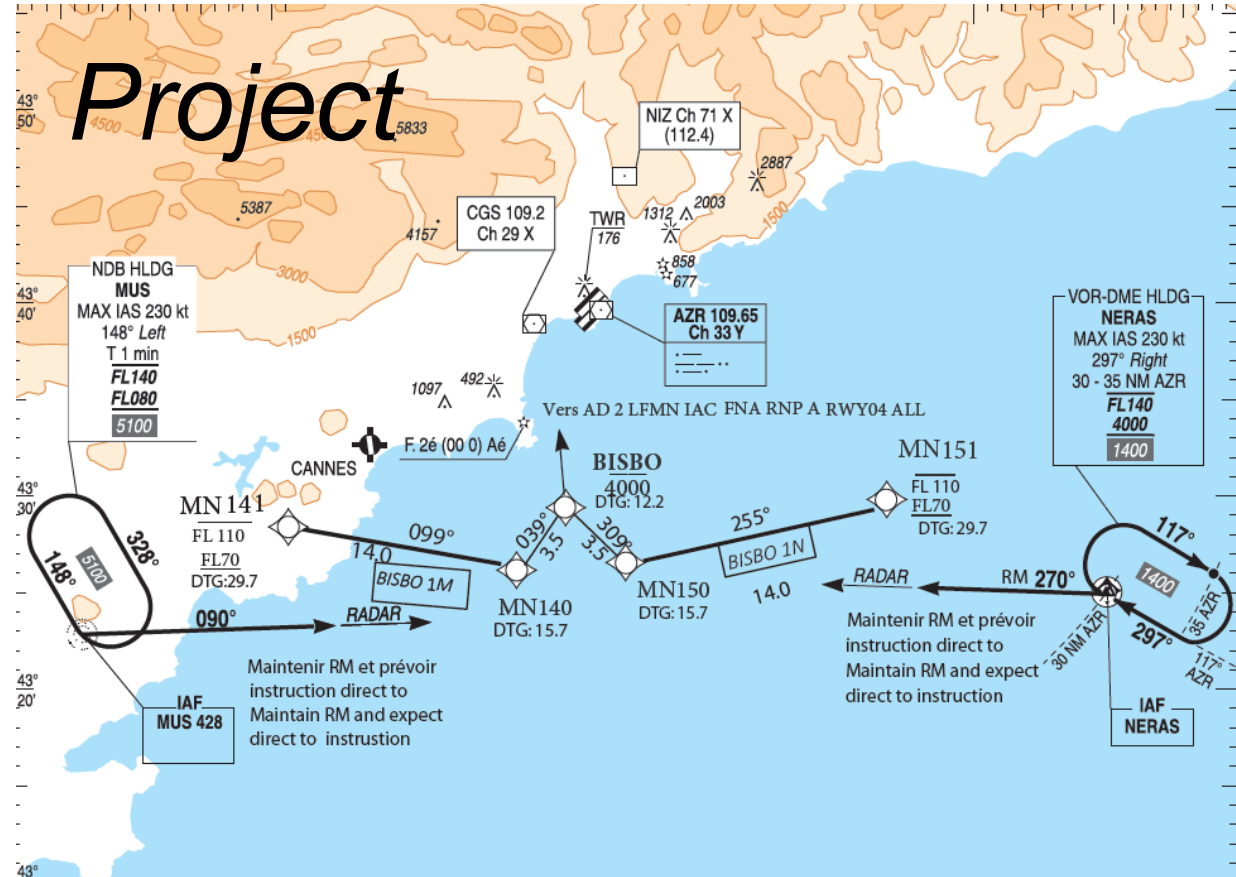

- Avoid high energy approach
- No impact during pick hours → no change in working methods during busy time

RNP A 04L/R

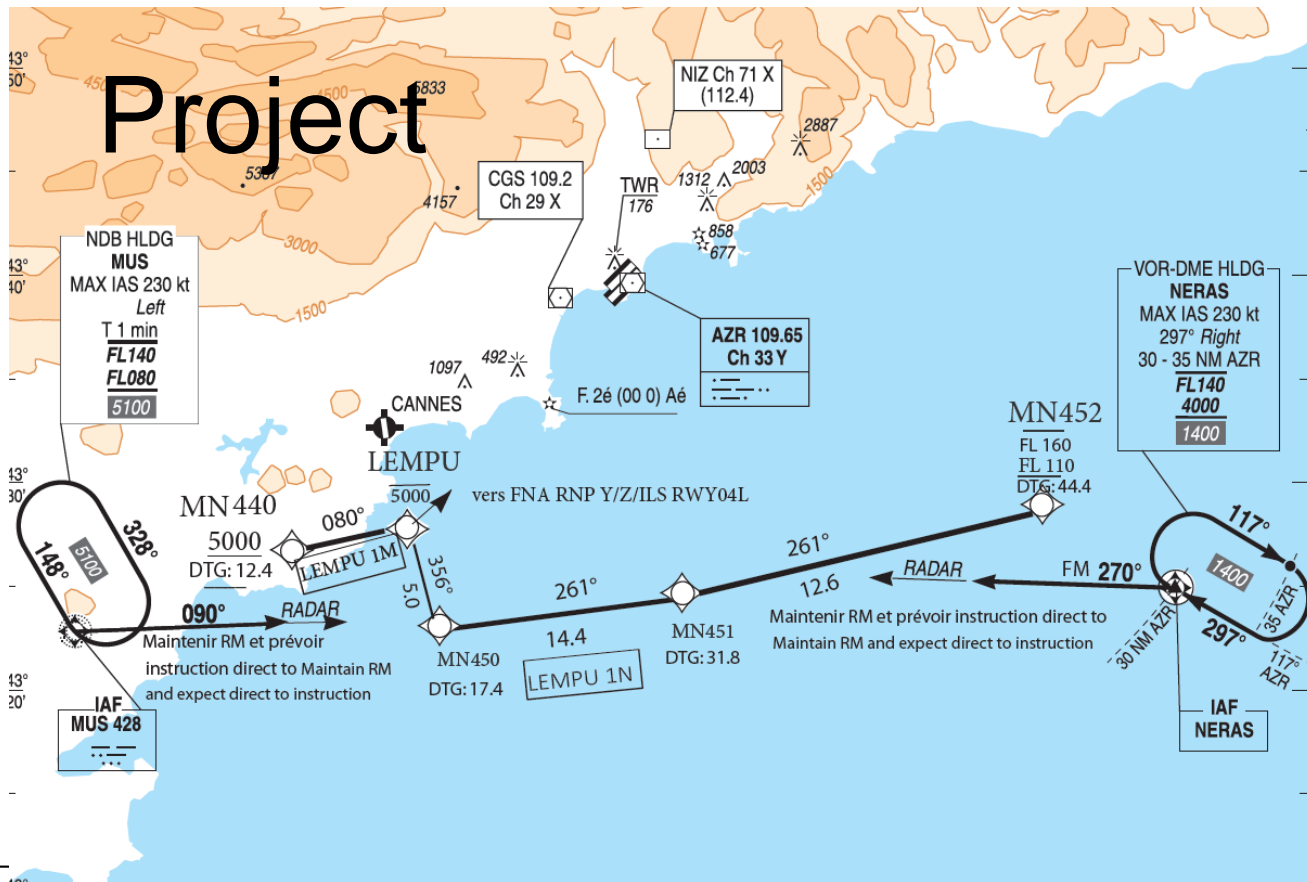

Project

PBN to Final :

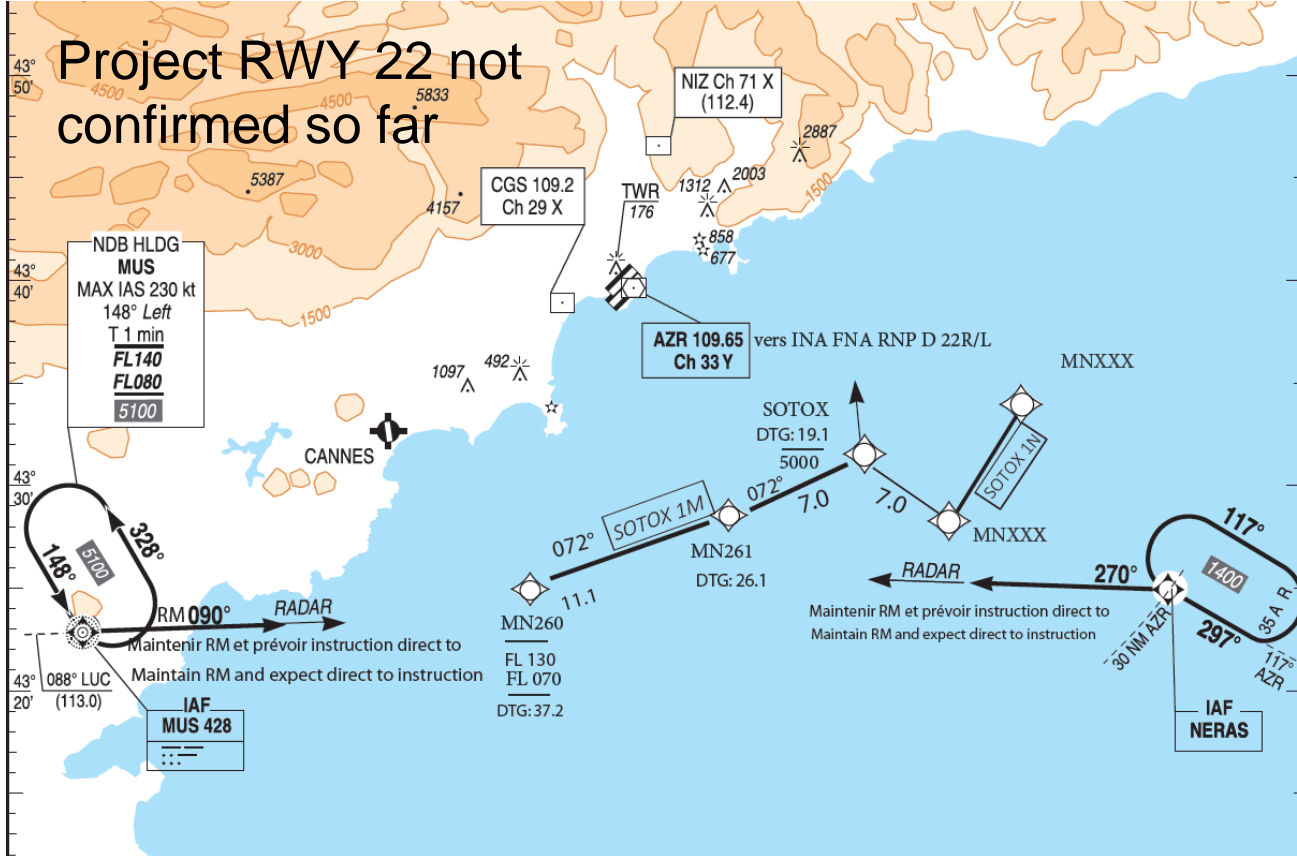

- starts from IAF with vectoring in the code : open « Dog legs »
- DCT possible at first contact from any entry point
- One chart for all kind of traffic !

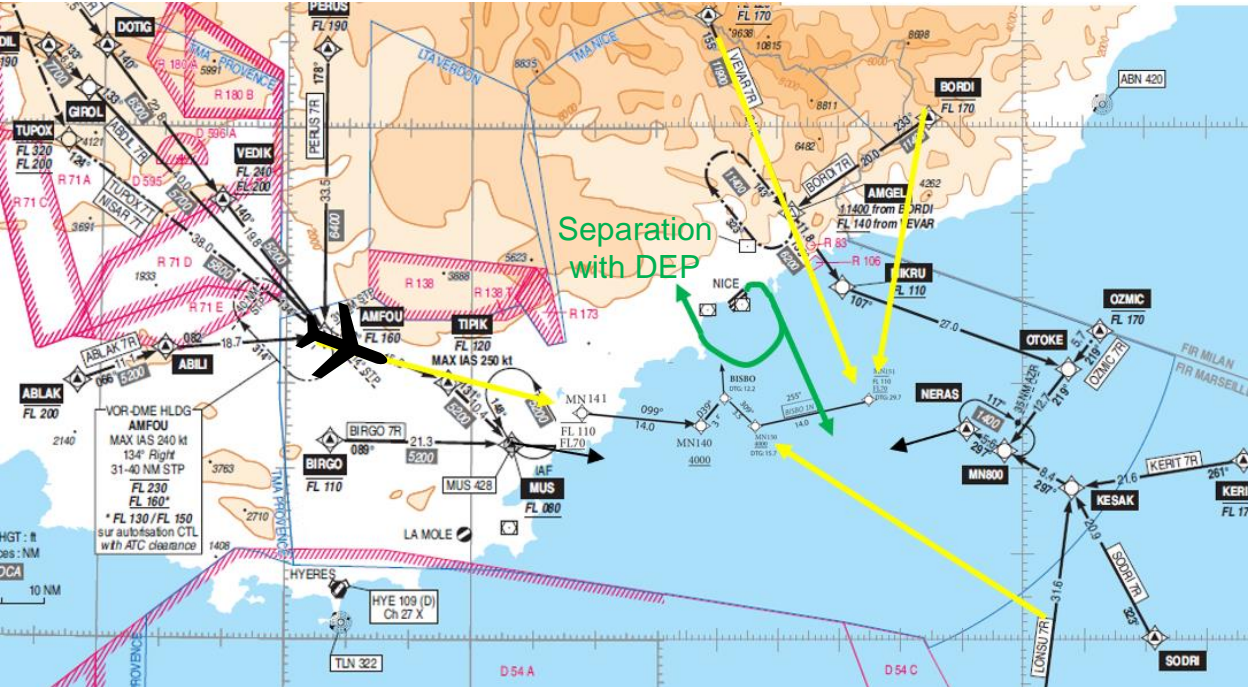

RNP Y/Z 04L/R

RNP D 22L/R

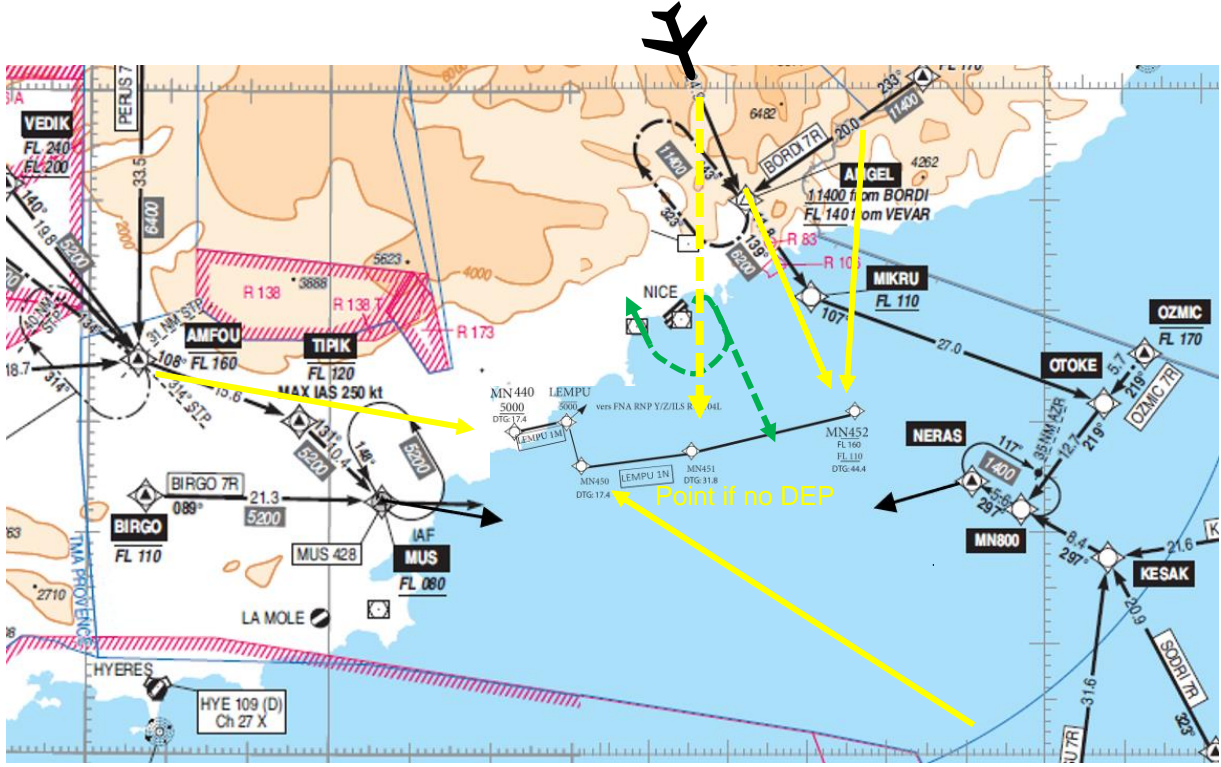

Exemple with RNP A 04 L/R

- DCT ASAP : End of vectoring
- DTG available → pilots manage descent
- Optimised distances
- Compromise with some departure tracks to increase the use
- Sequencing tool would increase the use

Exemple with ILS RNP Y/Z 04

Phraseology, for an arrival from the North :

- “XPE732, Bonjour, expect LEMPU1N (transition) then RNP Z 04L approach”
- “XPE732, Direct MN452, descend FL140 »

When cleared of terrain...

- “XPE732, **Continuous descent** via LEMPU1N to 4000ft QNH 1010”
- « XPE732, Cleared RNP Z 04L »

PBN to Final experimentation to improve CDO rate

Strategy of design :

- Optimise the distance flown → shortcut in departure sector
- Limit the time of radar vectoring → Waypoints located on optimised tracks
- Give the pilots DTG at first contact or ASAP with closed trajectory → Predictability
- Reduced constraints on Waypoints to let the FMS manage the VFE
- Starting at IAF → Avoid the risk of unexpected from STARs
- Containing a vectoring after IAF → transition usable all the time :
 - **Low traffic : early DCT to intermediate points => closing trajectory**
 - **Heavy traffic : vectors to Initial Fix (as usual)**

Next steps

- **Assess** and **adapt** the project with feedbacks from ATCOs, Air France and other AOs + data from ACROPOLE Tool
- Include **ACC** in live trial: Optimised ToD on selected flights
- Develop sequencing tools to increase the use with more traffic

Questions ?
